ABSTRACT

Objective: To determine the positioning of the most important livestock production chains in Zacatecas, Mexico, within a matrix of socioeconomic importance and market competitiveness, and to identify research and technology transfer needs.

Design/Methodology/Approach: Arranging livestock production chains into a hierarchy was carried out based on the methodology proposed by the International Service for National Agricultural Research (ISNAR), taking as analysis axis the dimensions of socioeconomic importance and competitiveness. The six most outstanding livestock production chains in the state were selected.

Results: The results placed the beef cattle chains as sustainable, the goat and sheep chains were placed as vulnerable, pork and honey were located in the retraction quadrant due to their low socioeconomic importance and competitiveness, and dairy cattle was placed in the strained quadrant.

Study Limitations/Implications: It is important to take into account other links.

Findings/Conclusions: Strategies for livestock production chains involve making the production more efficient through sustainable practices, providing technical assistance to producers, conducting research to generate technology, investing in infrastructure, and generating products with added value that meet the needs of consumers.

Keywords: Production chains, indicators, technologies.

INTRODUCTION

Zacatecas, Mexico, is considered a potentially rich state for livestock production, as it has more than 5 million hectares dedicated to grazing, with soils conducive to the development of good quality pastures and native grasses (Poaceae) of high forage value (Sánchez et al., 2015). The livestock sector in the state of Zacatecas generated a production value equal to 5.6 million pesos during 2017, within which beef cattle production accounted for 56% of the state production value with a contribution of $3.1 million pesos, through the production of 45,501 tons of meat. The second place was occupied by the dairy subsector, with 19.4% which generated $1.1 million pesos from the commercialization of 186,483 liters of milk (SIAP, 2017).
Livestock activities in the state represent a source of employment and income for the rural population. However, in order to improve productivity and quality to meet the demands of domestic and international markets, it is imperative to adapt and adopt technological changes and, therefore, optimize competitiveness. To achieve competitiveness in agrifood chains, the sector must design sectoral regulations that take into account not only the links involved in production, but also the options for specialization and interactions between production and the environment (Díaz and Hartley, 2006). To study the differentiated competitiveness of agricultural systems-products, the analysis of agricultural chains has been suggested (Antúnez and Ferrer, 2016).

Research on agro competitiveness and socioeconomic importance has been conducted in the state of Zacatecas (Sánchez et al., 2013; Rincón et al., 2004). However, the dynamism of production chains requires continuous monitoring, and previous studies have not focused on livestock production chains. Therefore, the objective of this study was to determine the positioning of the most important livestock production chains in Zacatecas, within a matrix of socioeconomic importance and market competitiveness, and to identify research and technology transfer needs. The information generated by this type of study will help decision-makers to efficiently direct financial, technological and research resources to each of the production chains.

MATERIALS AND METHODS
The study was carried out in 2019 in Zacatecas, Mexico, with the search of secondary information through the Service for Agrifood and Fishery Information (Servicio de Información Agroalimentaria y Pesquera, SIAP, 2017). A total of six livestock production chains were included, which were defined according to their economic and social importance in the state. The methodology does not consider a static point, but rather the trend over the last five years.

The methodology proposed by the International Service for National Agricultural Research (ISNAR) (Pardey and Roseboom, 2004) was used to rank the livestock production chains in Zacatecas according to weighted criteria, in order to identify strategic production chains through dimensionless values. Two guidelines were considered for this study: a) the socioeconomic relevance of the production chains; in other words, this axis considered attributes that justified the productive activity of each chain, due to their relevance; and b) competitiveness, which is an axis that explains the capacity of those involved in a production chain to face the challenges of change and their ability to adapt and overcome them.

To analyze socioeconomic importance, the following indicators were considered: a) Size: this concept refers to the dimension of the livestock production chain in terms of production value and contribution to the state’s economy; the area occupied by the number of heads of livestock species and the number of day laborers required for the activity were estimated; b) Dynamism: it represents the trend of production value and was presented with a simple linear regression for each chain. The slope indicated the rate of change of prices per unit of time. This section also evaluated the evolution of real prices by calculating the mean and standard deviation of the last five years, as well as the slope of the jobs produced in the state by the production chain; c) Specialization: it identified the level of specialization and economic concentration.

Competitiveness was studied using the following parameters: a) Productivity: this was based on three items: 1) relative productivity: [(state yield per chain)/(national yield per chain)] and 2) labor productivity, which was estimated by dividing the cost invested in wages by gross income; b) Sustainability: it considers soil erosion estimated from the universal soil loss equation (USLE) (Wischmeier and Smith, 1978), in this case the mean state erosion value per chain was used. Similarly, water efficiency and contamination from the use of fertilizers were analyzed, and for these sections a group of expert researchers (18 individuals) was formed to evaluate both aspects; c) Commercial performance: this variable was estimated based on the trend of real prices, which were obtained through the slope of the simple linear regression model of the price values (this value was considered as the exchange rate per unit of time).

All criteria or variables were standardized to zero mean and standard deviation of one, in order to have variables with equal magnitude and units (standard deviations) (Sanchez et al., 2013). Thus, the positioning matrix with the two reference axes, weighted and accumulated, was obtained. The results generated by the standardized matrix were presented as an interaction between the axes of a graph with four quadrants that indicate the positioning of each of the production chains (Jolalpa et al., 2013).
al., 2010). The data were analyzed with the Microsoft Excel software.

RESULTS AND DISCUSSION
It was found that there are six major livestock production chains in Zacatecas, so they were prioritized. Analysis of the information made it possible to rank the livestock chains according to the sum of all their indicators, their relative value and their hierarchy. The results indicated that the most important production chain was dairy cattle, followed by beef cattle, sheep, goats, honey and pork (Table 1).

Integration of the information made it possible to locate the livestock production chains in the positioning matrix, which formed four groups according to the socioeconomic relevance and competitiveness of each chain in the state of Zacatecas (Figure 1).

In 2013, the beef cattle chain ranked 0.7 in competitiveness and 1.7 in socioeconomic importance; six years later, this chain ranked 1.1 and 0.4 in competitiveness and socioeconomic importance, respectively. This showed that beef cattle decreased in competitiveness, but increased its socioeconomic importance. Nevertheless, this chain obtained the greatest socioeconomic and competitive importance (Figure 1, Quadrant I). This was sustained in the 2015-2016 cycle, where 31,769 head were exported; with this, the state ranked sixth nationally in live cattle exports to the United States (FAOSTAT, 2017). However, for this chain to continue to be sustainable, it is imperative to guarantee safety and to produce excellent quality meat in the shortest possible time, in order for the livestock enterprise to be efficient and profitable. In terms of the international market, quality is considered to be that which contains high muscle content and sufficient intramuscular fat (marbling) to satisfy the organoleptic requirements of the consumer (Monsón et al., 2005).

At the same time, all market segments must be taken into account, for which one of the options is to opt for the minimum processing of the product (from live animals to meat cuts). With the minimum process, the profitability of the farmer increases, since the price received per standing calf is $28 per kg and up to $40 per kg of bull calf; while the average price per cut varies between $90 and $140 per kg of meat (SNIIM, 2019), which means 250% increase. This explains that much of the price is generated within the commercialization process through minimal processing of the product (from live animals to meat cuts), transportation (from the production area to the consumption centers), and from there to international distribution.

It is also necessary for farmers to become involved in the commercial process in order to reduce the number of intermediaries involved in the chain. Studies indicate that, from calf collection to the final consumer, there are between 5 and 10 links in the chain; and, depending on the flowchart of the chain, the participation time for each agent varies from one day (stockers, wholesalers and slaughterers) to four to eighteen months (fatteners and breeders) (Licea et al., 2015).

Market opportunities for this chain in Mexico are high, despite the fact that beef consumption has declined, but its nutritional and economic

</table>
importance is high; in 2000 more than 22 kg per capita were consumed, but in 2016 there was a significant decrease (14.9 kg per capita) (SIAP, 2017). This reduction in consumption was due to the sustained increase in per capita consumption of chicken meat (29.2 per capita) (SIAP, 2017), and the recovery in pork consumption (16.6 kg per capita) (SIAP, 2017). Consequently, marketing strategies must be implemented to maintain and promote the positioning of the beef cattle production chain.

At the reproductive level, farmers in the region must pay attention to improving the genetic quality of cattle to obtain better yields. Genetic improvement through the acquisition of registered sires is vital to increase the quality and productivity of cattle herds and, therefore, to achieve a significant improvement in the technical and economic parameters of the activity (Carrera, 2008).

The goat and sheep chains are in the vulnerable quadrant (Figure 1, Quadrant II). In 2019, these production chains were competitive, but they require greater social and economic importance. The negative values in the socioeconomic axis are due to the low number of heads per herd, the decrease in the production value, and the few day laborers used to carry out productive activities. Low precipitation in Zacatecas (less than 400 mm in some areas) has reduced crop productivity and the availability of grass forage which has led to a decrease in the herd (Echavarría et al., 2014). Despite this, the momentum of these chains is preponderant as it contributes to the survival of low-income producers, providing food and income (Echavarría et al., 2015). Therefore, in order to move these production chains from a state of impulse to one of high strategic priority, technology transfer projects must be implemented to reduce the seasonality of reproduction, since the offspring are born in late winter and early spring, when the highest end-of-year market demand has already passed; this decreases profits and is the longest period of drought, which reduces the availability of grasses, leading to increased mortality rates or low development rates. Thus, it is necessary to breed at times that guarantee births at the beginning of the rainy season, that is, to change the reproductive cycle (López et al., 2011).

Likewise, it is necessary to develop abilities in farmers to improve management practices (Salinas and Rumayor, 1999) and reduce animal health problems (Echavarría et al., 2010). Similarly, it is imperative to add value to primary production and to focus products on specialized segments. Segmentation allows producers to avoid head-on competition in the market by differentiating offers, not only on the basis of price but also in terms of product characteristics, advertising messages, and distribution methods (Fernández and Aqueveque, 2001).

In 2019, the pork and honey production chains were positioned in quadrant III, with low socioeconomic importance and low competitiveness in the state context. These chains have been introduced recently to the State, and were characterized by low dynamism and innovation, low pay for workers, and a marked inability to generate jobs. From 2013 to 2019 these chains dropped from quadrant II to quadrant III (Figure 1). The change in dynamism of the pork and beekeeping sectors (vulnerable quadrant to retraction quadrant) in this region was due to a combination of various factors specific to the state and the macroeconomic and sectoral policies adopted by Mexico as a result of trade liberalization. This had an impact on the development of the agricultural sector, especially the pork production sector. The withdrawal of government subsidies to pig farmers caused a decrease in the activity by consolidating the most efficient companies and eliminating the semi-technified ones (García et al., 2004). This event generated variations in pork production growth rates and different effects among the country’s regions. Thus, the pork production chain in the state remained a slow-growing activity, because of inefficient use of resources, low productivity and a low degree of technification; this led to it being classified as a lagging region (Rebollar et al., 2015). The strategy should be to increase technical assistance in terms of health, nutrition, vaccination and biosecurity programs, and to improve infrastructure and seek alternative marketing channels.

The beekeeping chain in Zacatecas has low production (2,077 t), but stands out nationally for its quality and amber color. The honey commercialization process in the state is carried out directly by the beekeeper or family members and is packaged in containers with many presentations. Among the factors that influenced its low production are the indiscriminate use of pesticides, high feed costs, poor genetic quality of queen bees and weather conditions, particularly the drought in 2011, which worsened in 2012, resulting in low flora, water scarcity and death due to hypothermia and diseases that attack the insect (Secretaría del Campo, 2018).
The importance of pollinating insects in global food production is undisputed, and it can be argued that it will become increasingly important in a context of increasing food production needs and declining pollinators, especially the domestic honeybee (Miñarro et al., 2018).

Sustainable agricultural practices, and in particular agroecology, can help protect bees by reducing exposure to pesticides and helping to diversify agricultural landscapes (FAO, 2017). Consequently, the strategy for this chain includes projects that promote bee health, technology transfer to increase productivity and safety, pesticides and practices that help reduce the exposure of pollinators, as well as research and investment in infrastructure.

Innovations related to feeding, milk quality, genetics and technical assistance are the most relevant in the family dairy production system. In family systems, feeding is the main cost of production, but at the same time, if it is done properly, it represents an opportunity: silage feeding allows sustaining livestock production throughout the year, avoids the seasonality of milk production, reduces losses caused by poor feeding, and increases milk production and profitability (Raymond et al., 1989).

CONCLUSIONS
The strategic positioning of the chains indicated that the beef cattle chain was sustainable, the goat and sheep chains were vulnerable, the pork and honey chains were in retraction due to their low socioeconomic importance and competitiveness, and the dairy cattle chain was a strained chain. The strategies for livestock production chains are to be efficient in production through sustainable practices, to provide technical assistance to producers, to conduct research to generate technology, to invest in infrastructure, to generate value-added products that meet the needs of consumers, and to seek short commercialization channels.
